Interpolation

Interpolat

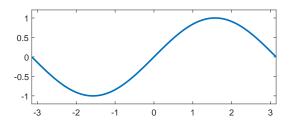

Polynomials Splines

Approximating functions

How does a calculator compute evaluations of complex functions like

$$f(x) = \sin(x),$$

despite only having units that can do basic operations like addition and multiplication?

First possible idea: Taylor expansion to obtain a polynomial

$$\sin(x) \approx \sum_{i=0}^{n} \frac{(-1)^{i}}{(2i+1)!} x^{2i+1}$$
?

For $n \to \infty$ the approximation converges to the sine function.

Interpolation and Integration

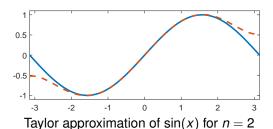

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

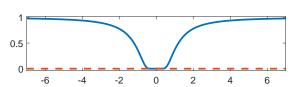

Approximating functions

Faithful around zero, poor at the boundary.

Furthermore, Taylor approximations can be treacherous, consider the approximation around zero of

$$f(x) = \begin{cases} \exp(-1/x^2) & \text{ for } x \neq 0, \\ 0 & \text{ otherwise.} \end{cases}$$

Interpolation and Integration

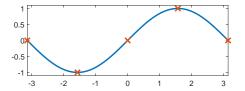

Michael Moeller

Interpolation Polynomials

Splines Integration Let us consider a different idea that aims at approximating the function well in the entire interval.

How about sampling the function at a few specific points with high accuracy and then computing a polynomial curve through the sample points?

We already know one way to solve this: For n sampling points we use a polynomial of degree n-1, i.e.,

$$p(x) = \sum_{i=0}^{n-1} a_i x^i,$$

and form a linear system from the equations $p(x_j) = y_j$ for all n many sampled points (x_i, y_i) .

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

A different way to immediately state the polynomial without solving a linear system is to consider

$$I_{jn}(x) = \frac{(x-x_1)\dots(x-x_{j-1})(x-x_{j+1})\dots(x-x_n)}{(x_j-x_1)\dots(x_j-x_{j-1})(x_j-x_{j+1})\dots(x_j-x_n)}.$$

Note that $I_{jn}(x_j) = 1$ as the nominator and denominator are equal, and that $I_{jn}(x_i) = 0$ for all $i \neq j$.

This motivates to use

$$p(x) = \sum_{j=1}^{n} I_{jn}(x) y_{j}$$

as the interpolation polynomial:

- The l_{jn} are polynomials of order n-1 and so is p,
- and obviously $p(x_j) = y_j$ for all j,

which means we found our desired polynomial.

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

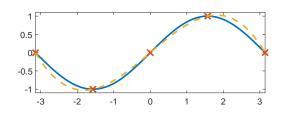

Polynomials Splines

There is a lot of theory for efficiently determining interpolation polynomials. The previous form is called **Lagrange form**.

Newton polynomials with divided differences are a different popular form in the literature.

We have too little time to understand the computational advantages of each form in detail. Naturally, they all describe the same polynomial.

Returning to our sine example, we obtain the following result

Seems ok - but what if the functions are more complicated?

Interpolation and Integration

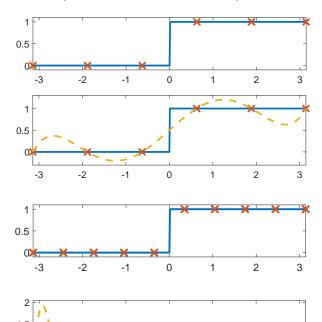

Michael Moeller

Interpolation

Polynomials Splines

Consider a step function and refine the interpolation

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

Reason: If we approximate a function $f:[-1, 1] \to \mathbb{R}$ that is n times continuously differentiable by an interpolation polynomial p of degree n-1, one can show that

$$f(x) - p(x) = \frac{f^{(n)}(\xi)}{n!} \prod_{i=1}^{n} (x - x_i)$$

for some $\xi \in [-1, 1]$, where the x_i are the points with $p(x_i) = f(x_i)$.

For equally spaced x_i the term $|\prod_{i=1}^n (x - x_i)|$ is much larger at the boundary of the interval.

Natural idea: Choose the nodes x_i such that

$$\max_{x\in[-1,1]}\left|\prod_{i=1}^n(x-x_i)\right|$$

is minimal.

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

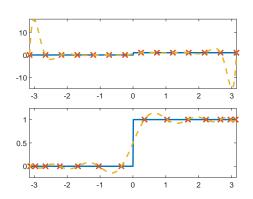

Chebyshev roots

One can show that the problem of choosing the nodes x_i such that

$$\max_{x \in [-1,1]} \left| \prod_{i=1}^{n} (x - x_i) \right|$$

is minimal can be achieved by picking x_i to be the **Chebyshev** roots

$$x_i = \cos\left(\frac{2i-1}{2n}\pi\right), \quad i=1,\ldots,n.$$

Interpolation and Integration

Michael Moeller

Interpolation

Polynomials Splines

We have just seen an example of using an interpolation polynomial with Chebyshev roots, which tried to minimize the maximal pointwise error bound.

This rises the systematic idea to call p^* a **best approximation** of a function f in some set T of candidate functions with respect to the norm $\|\cdot\|$ if

$$\|p^*-f\|\leq \|p-f\| \qquad \forall p\in T.$$

Will will now consider two examples, both of which choose T to be the set of polynomials of degree n, and

- $\|\cdot\|$ being the L^2 norm
- $\|\cdot\|$ being the L^{∞} norm

One can show that

$$\langle f,g\rangle := \int_{-1}^1 f(x) \cdot g(x) \ dx$$

defines a scalar product on the space of continuous functions.

The induced norm

$$||f||_2 := \sqrt{\langle f, f \rangle}$$

is called the L^2 norm, and is one of the most commonly used norms in visual computing.

Question: How can we find the best approximation of a given function f with a polynomial p in the sense of the L^2 -norm?

Reminder: Orthogonal systems in linear algebra

We say that two vectors f and g of some vector space V with an inner product $\langle \cdot, \cdot \rangle$ are **orthogonal**, if

$$\langle f,g\rangle=0.$$

We will show in the exercise:

Best approximation

Let v_1, \ldots, v_n be pairwise orthogonal with $||v_i|| = 1 \ \forall i$. For any $f \in V$ it holds that

$$\sum_{i=1}^n \langle v_i, f \rangle v_i$$

is the best approximation of f in span (v_1, \ldots, v_n) .

How can we use this result for finding a best polynomial fit?

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

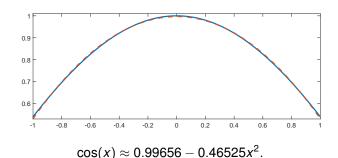

Best polynomial L² fit

Surely, 1, x, x^2 , ..., x^n is a basis of the polynomials of degree n.

Idea: Use the Gram-Schmidt technique to form an orthonormal basis. \rightarrow Board!

$$v_1(x) = \frac{1}{\sqrt{2}}, \quad v_2(x) = \sqrt{\frac{3}{2}}x, \quad v_3(x) = \sqrt{\frac{5}{8}}(3x^2 - 1).$$

Example: Approximating the cosine

Interpolation and Integration

Michael Moeller

Interpolation Splines

Polynomials

The fact that

$$\sum_{i=1}^n \langle v_i, f \rangle v_i$$

is the best approximation of f in span (v_1, \ldots, v_n) is of course not limited to polynomials, but holds for any orthonormal system.

Prominent example:

$$\left\{\frac{1}{2},\cos(\pi x),\sin(\pi x),\cos(2\pi x),\ldots,\cos(n\pi x),\sin(n\pi x)\right\}$$

on [-1, 1] with the L^2 norm. In this case the inner products $\langle v_i, f \rangle$ are also known as the **Fourier coefficients**.

Next question: What if we change the measure of approximation quality?

Instead of looking for the best L^2 approximation, let us try to find the best polynomial L^{∞} approximation, i.e. find a polynomial p of degree n such that

$$||f - p||_{\infty} := \max_{x \in [-1,1]} |f(x) - p(x)|$$

is minimal among all possible polynomials p of degree n.

Difficulty: The L^{∞} norm is not induced by a scalar product! We cannot look for an orthogonal basis – there is no notion of orthogonality!

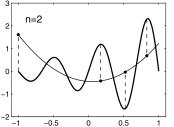

Best L^{∞} -norm approximation

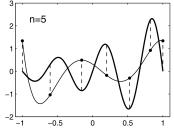

Math is great! :-) People have proven the following theorem to still determine an algorithm:

Equi-oscillation property

A polynomial p of degree n is the best L^{∞} approximation to a continuous function $f:[-1,\ 1]\to\mathbb{R}$ if and only if there exists a set of n+2 distinct points x_i and $\sigma\in\{-1,1\}$ such that

$$f(x_i) - p(x_i) = \sigma (-1)^i \|f - p\|_{\infty}, \qquad i = 0, ..., n + 1,$$

 $From: \ Pachon, \ Trefethen: \ Barycentric-Remez \ algorithms \ for \ best \ polynomial \ approximation \ in \ the \ chebfun \ system.$

Interpolation and Integration

Michael Moeller

Interpolation

Polynomials Splines

The **equi-oscillation property** allows to develop an algorithm for determining best L^{∞} approximations.

First of all note that for given $x_0 < \ldots < x_{n+1}$ there exists a (unique) polynomial p of degree n and a constant D such that

$$f(x_i) - p(x_i) = (-1)^i D$$

hold for all $i = 0, \ldots, n + 1$.

Reason: A polynomial of degree n has n+1 free parameters. The constant D is an additional free parameter, i.e., we have n+2 linear equations and n+2 unknowns. The property $x_0 < \ldots < x_{n+1}$ ensures that the linear system has a unique solution.

Idea for an algorithm:

- **1** Sample the interval [-1,1] uniformly to obtain initial guesses for x_0, \ldots, x_{n+1} .
- 2 Compute the polynomial *p* and the constant *D* that satisfy

$$f(x_i) - p(x_i) = (-1)^i D \quad \forall i.$$

- 3 If $D = \|p f\|_{\infty}$, the equioscillation property tells us that we found the best L^{∞} approximation.
- 4 If $D < \|p f\|_{\infty}$, slightly move the x_i such that $|p(x_i) f(x_i)|$ increases, and return to 2.

 $oldsymbol{0}$ Compute the polynomial p and the constant D that satisfy

$$f(x_i) - p(x_i) = (-1)^i D \quad \forall i.$$

2 For each x_i compute

$$e_i^1 = f(x_i) - p(x_i), \quad e_i^2 = f(x_i + \epsilon) - p(x_i + \epsilon)$$

3 If
$$e_i^1 > 0$$
 and $e_i^1 > e_i^2$ or if $e_i^1 < 0$ and $e_i^1 < e_i^2$, update $x_i \leftarrow \max(x_i - \tau, -1)$

4 Otherwise update

$$x_i \leftarrow \min(x_i + \tau, 1)$$

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation

Polynomials Splines

¹For more details see, e.g., Barycentric-Remez algorithms for best polynomial approximation in the chebfun system.

- We approximate a continuous function $f:[-1,1] \to \mathbb{R}$ with polynomials.
- A simple (but unreliable) version is to compute the interpolation polynomial for uniformly sampled points $(x_i, f(x_i))$.
- The results often improve drastically if one chooses the sample points x_i as the Chebyshev roots

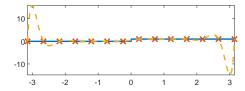

$$x_i = \cos\left(\frac{2i-1}{2n}\pi\right), \quad i=1,\ldots,n.$$

- More systematically, one can compute the best approximation of f with respect to a given norm.
 - For the L^2 norm we compute orthonormal basis and use $\langle v_i, f \rangle$ as the coefficients.
 - For the L^{∞} norm we can use the equioscillation property to develop efficient algorithms.

Splines

So far, we have mostly considered polynomials to approximate functions and solve interpolation problems.

As we have seen in examples like

polynomials of high degrees can quickly show oscillatory behavior.

In practice one almost never uses polynomials of high degree (\geq 10) for any interpolation problem.

Much smoother version: So called splines.

Interpolation and Integration

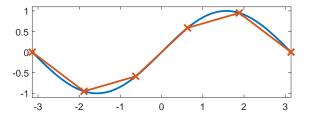

Michael Moeller

Interpolation Polynomials Solines

Spline interpolation

While the name **spline** might sound fancy, it is the most natural idea for interpolation: Use a piecewise polynomial function (with polynomials of low degree) for interpolation.

A linear spline is nothing but the piecewise linear function

$$s(x) = \frac{x - x_i}{x_{i+1} - x_i} f(x_{i+1}) + \left(1 - \frac{x - x_i}{x_{i+1} - x_i}\right) f(x_i), \quad \text{for } x \in [x_i, x_{i+1}].$$

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation Polynomials

Splines Integration The drawback of linear splines is that the resulting approximation *s* is not differentiable.

To have more freedom and impose more regularity one can utilize higher order piecewise polynomial functions.

Example: Cubic splines are of the form

$$s(x) = a_i x^3 + b_i x^2 + c_i x + d_i$$
, for $x \in [x_i, x_{i+1}]$.

For linear splines we had two end-points that fully determined the two coefficients of a linear function. How do we determine the coefficients of cubic splines?

Spline interpolation

Usual choice: So called C^2 splines, i.e., a piecewise cubic function that is two times continuously differentiable.

Let
$$s_{|[x_i,x_{i+1}]}(x) = a_i x^3 + b_i x^2 + c_i x + d_i$$
. We require

$$s_{|[x_i,x_{i+1}]}(x_i) = y_i \tag{1}$$

$$s_{|[x_i,x_{i+1}]}(x_{i+1}) = y_{i+1}$$
 (2)

$$s'_{|[x_{i-1},x_i]}(x_i) = s'_{|[x_i,x_{i+1}]}(x_i)$$
(3)

We have 4 coefficients for each of the
$$n-1$$
 many $s_{|[x_{i-1},x_i]}$, i.e. $4(n-1)$ many unknowns.

 $s''_{|[x_{i-1},x_{i}]}(x_{i}) = s''_{|[x_{i-1},x_{i-1}]}(x_{i})$

We have n-1 many equations from (1), n-1 many equations from (2),

n-2 many equations from (3),

n-2 many equations from (4),

i.e., 4(n-1) - 2 equations in total.

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation Polynomials

Integration

Splines

(4)

Spline interpolation

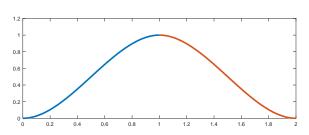

What do we do with the two extra degrees of freedom?

Most common choice: Natural C^2 spline, i.e., additionally require

$$s'_{|[x_1,x_2]}(x_1) = 0,$$
 (a)
 $s'_{|[x_{n-1},x_n]}(x_n) = 0.$ (b)

$$s'_{|[X_{n-1},X_n]}(x_n)=0.$$
 (b)

Instructive computation on the board: Set up the linear equations for a natural C^2 spline going through the points

Interpolation and Integration

Michael Moeller

Interpolation Polynomials Splines

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation
Polynomials
Splines

Integration

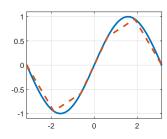

Integration in 1d

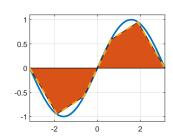

Let us first consider the 1d integral

$$\int_a^b f(x) \ dx.$$

The general strategy is to approximate *f* by a function that is easy to integrate, e.g., by a spline function and use the integral over the approximate function instead!

Example: Trapezoidal rule

Interpolation and Integration

Michael Moeller

Interpolation
Polynomials
Splines

Trapezoidal Rule

To approximate a function f linearly on an interval $[t_{i-1}, t_i]$ one

$$f_{approx}^{i}(x) = \frac{t_{i} - x}{t_{i} - t_{i-1}} f(t_{i-1}) + \left(1 - \frac{t_{i} - x}{t_{i} - t_{i-1}}\right) f(t_{i}).$$

One finds that

uses

$$\int_{t_{i}}^{t_{i}} f_{approx}^{i}(x) dx$$

$$\int_{t_{i-1}} I_{approx}(X) \ dX$$

$$= \int_{t}^{t_i} f(t_i) dx + (f(t_i) - f(t_{i-1})) \int_{t}^{t_i} \frac{t_i - x}{t_i - t_{i-1}} dx$$

$$= \int_{t_{i-1}}^{t_i} f(t_i) dx + (f$$

$$\int_{t_{i-1}}^{t_i} f(t) dt + (f(t)) dt$$

$$= \int_{t_{i-1}}^{t_i} f(t_i) dx + (f(t_i) - f(t_{i-1})) \left[\frac{xt_i - 0.5x^2}{t_i - t_{i-1}} \right]_{t_{i-1}}^{t_i}$$

$$= (t_i - t_{i-1})f(t_i) + (f(t_i) - f(t_{i-1}))\frac{0.5t_i^2 - t_it_{i-1} + 0.5t_i^2}{t_i - t_{i-1}}$$

$$= (t_i - t_{i-1})f(t_i) + \frac{1}{2}(f(t_i) - f(t_{i-1}))(t_i - t_{i-1})$$

$$= \frac{1}{2}(f(t_i) + f(t_{i-1}))(t_i - t_{i-1})$$

Visual Scene

> Interpolation Polynomials Splines

Interpolation and

Michael Moeller

Trapezoidal Rule

Therefore one approximates

$$\int_a^b f(x) \ dx \approx \sum_{i=1}^n \int_{t_{i-1}}^{t_i} f_{approx}^i(x) \ dx$$

for
$$t_0 = a$$
 and $t_i = a + h i$, $h = \frac{b-a}{n}$.

We find

$$\int_{a}^{b} f(x) \ dx \approx h \left(\frac{f(t_0)}{2} + \frac{f(t_n)}{2} + \sum_{i=1}^{n-1} f(t_i) \right)$$

the trapezoidal rule.

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation
Polynomials
Splines

egration

Higher order approximation

As long as the function f one tries to approximate is smooth (varying slowly) the accuracy of the integral improves as one approximates the function within each interval by a higher order polynomial.

If the interval [c, d] is sampled at points

$$x_i = c + h \cdot \frac{i}{n}, \qquad h = d - c, \qquad i = 0, \dots, n$$

and one fits a polynomial of degree *n* through them,one obtains the **Newton-Cotes** formula

$$\int_{c}^{d} f(x) dx = h \sum_{i=1}^{n} \alpha_{i} f(c + \xi_{i} h),$$

with α_i being the integrals over the **Lagrange polynomials**,

$$\alpha_i = \frac{1}{h} \int_c^d \prod_{i=0, i \neq j}^n \frac{x - x_j}{x_i - x_j} dx.$$

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation
Polynomials
Splines

egration

Higher order approximation

n	name	ξi	α_i
1	trapezoidal rule	0, 1	$\frac{1}{2}, \frac{1}{2}$
2	Simpson rule	$0,\frac{1}{2},1$	$\frac{1}{6}, \frac{4}{6}, \frac{1}{6}$
3	$\frac{3}{8}$ -rule	$0,\frac{1}{3},\frac{2}{3},1$	$\frac{1}{8}, \frac{3}{8}, \frac{3}{8}, \frac{1}{8}$

Interpolation and Integration

Michael Moeller

Visual Scene Analysis

Interpolation Polynomials Splines

ntegration

Example approximation by applying the Simpson rule to each interval $[t_{i-1}, t_i]$:

$$\begin{split} \int_{a}^{b} f(x) \ dx &\approx \frac{b-a}{n} \left(f(t_0) + 4f\left(\frac{t_1 - t_0}{2}\right) + 2f(t_1) + 4f\left(\frac{t_2 - t_1}{2}\right) \right. \\ &+ \ldots + 2f(t_{n-1}) + 4f\left(\frac{t_2 - t_1}{2}\right) + f(t_n) \Big) \end{split}$$

Higher order approximation

The Newton-Cotes formulas based on

$$\int_{c}^{d} f(x) dx = h \sum_{i=1}^{n} \alpha_{i} f(c + \xi_{i} h),$$

is exact for f being a polynomial of order n (at least).

One can also optimize the weights α_i and the points x_i at which the function is evaluated for being exact for a polynomial of maximal order. Surprisingly, one can get exact polynomial integration of order 2n + 1 with only n + 1 evaluations.

Such formulas are known under the name of **Gauß quadrature**. We will not detail those more sophisticated methods here - in image processing simple piecewise constant or piecewise linear approximations are used most often.

Interpolation and Integration

Michael Moeller

Interpolation
Polynomials
Splines

Higher dimensional integration

In imaging, we often have to integrate functions $f:\Omega\subset\mathbb{R}^2\to\mathbb{R}$ which correspond to images and are therefore two-dimensional.

Note that we can reduce multi-dimensional integrals to multiple one-dimensional integrals, e.g., if $\Omega = [a, b] \times [a, b]$, then

$$\int_{\Omega} f(x) \ dx = \int_{a}^{b} \int_{a}^{b} f(x_{1}, x_{2}) \ dx_{1} \ dx_{2}.$$

Note that the common division of [a, b] into $[a = t_0, t_1]$, $[t_1, t_2]$, ..., $[t_{n-1}, t_n]$ now (at least) requires the evaluation of f at all $(n+1)^2$ points $f(t_i, t_j)$.

Since the complexity grows exponentially with the dimension of the space, other techniques (e.g. Monte Carlo methods) have to be applied for dimensions significantly larger than 2. Interpolation and Integration

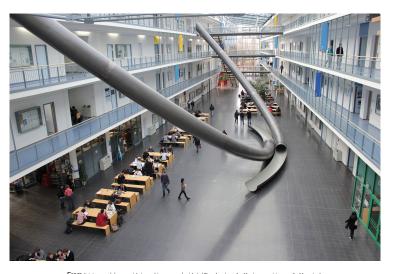

Michael Moeller

Interpolation
Polynomials
Splines

Line integrals

Sometimes, one has to evaluate the length of a path:

 $\textbf{From} \; \texttt{https://en.wikipedia.org/wiki/Technical_University_of_Munich}$

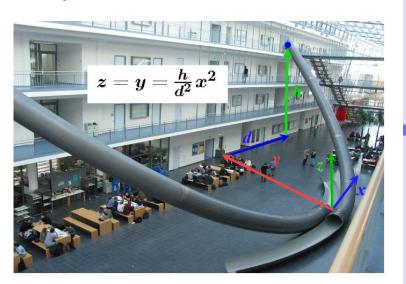

Interpolation and Integration

Michael Moeller

Interpolation
Polynomials
Splines

Line integrals

From https://www.ma.tum.de/Mathematik/Parabelrutsche

Step 1: Parameterize the path!

Interpolation and Integration

Michael Moeller

Interpolation
Polynomials
Splines

Line integrals

We can find a parametrization of the curve in 3d:

$$r: [0, d] \to \mathbb{R}^3$$

$$t \mapsto \left[t, \frac{h}{d^2} t^2, \frac{h}{d^2} t^2 \right]$$

Line integral

The **line integral** of a function $f: U \subset \mathbb{R}^n \to \mathbb{R}$ along a piecewise smooth curve $C \subset U$ is defined as

$$\int_a^b f(r(t)) \cdot |r'(t)| dt$$

where $r : [a, b] \to C$ is an arbitrary bijective parametrization of the curve C such that r(a) and r(b) give the endpoints of C and a < b.

Let's do this for the above example of deterimining the length, i.e., $f \equiv 1$.

Interpolation and Integration

Michael Moeller

Interpolation
Polynomials
Splines

Line integral

We find

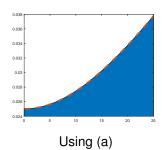

$$r'(t) = \left(1, \frac{2h}{d^2}t, \frac{2h}{d^2}t\right)^T$$

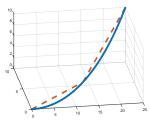

and therefore

$$\int_0^d \sqrt{1^2 + 2\frac{4h^2}{d^4}t^2} \ dt \tag{a}$$

is the length of the slide in Munich.

If |r'(t)| is too complicated to compute, we can of course also use a polygonal chain to approximate the length directly.

Using polygons
